2. The idea

CLEAR helps compliance analysts investigate anti-money-laundering (AML) alerts, gathering evidence automatically. While standard bank systems flag alerts with broad rules that result in about 95% false positives, our solution deploys a collaborative team of specialized AI agents to cross-check customer history, debate opposing laundering arguments, and cite regulations. Users will be able to manage an alert queue, review fully documented case files, and chat with an assistant to query specific case details. The system uses the IBM AML synthetic transactions dataset, with initial alerts triggered via structured banking rules. The AI goes beyond ordinary code by orchestrating multi-agent tool calls, retrieving regulatory documents via RAG, running debates between the prosecution and the defense, and making sure every claim is backed up by evidence.

3. One interaction, end to end

The compliance analyst selects an alert from the queue to review a complex transaction spike. The user writes in the chat interface: "Summarize why the prosecution agent flagged this customer's cross-border transfers." The model receives the user query alongside the specific case file and the prosecution agent's historical arguments, and returns a structured breakdown citing specific transaction dates and regulatory sections. Our code validates that every referenced citation maps to an existing log in the database, and the reply displays the verified argument summary directly in the analyst dashboard.
